THE ROLE OF DIFFUSION TENSOR IMAGING (DTI) IN SPINAL CORD PATHOLOGY

Hend Galal Eldeen Mohamed Ali Hassan *, Rania Ali Maarouf*, Mohamed Amr Farouk Abo-Elela** and Norhan Ramzy Mohamady***

ABSTRACT:

Background: Many patients complain from sensory deficient secondary to different causes, although the magnetic resonance (MR) shows the mass effect or changes of spinal cord yet it is still limited in predicting symptoms severity as patients may have a varying tolerance of spinal cord compression. Diffusion tensor imaging (DTI) shows could predict degree of spinal cord affection even with mild lesions.

Aim of the work: is to show the role of Diffusion tensor imaging(DTI) in proved different cervical or dorsal spinal lesions by conventional MRI.

Patients and Method: The study included 16 patients divided into 6 patients complaining from compressive disc lesions with sensory deficient, 2 patients with neoplasm complain from newly developed sensory deficient patients with and 8 patients complaining from internal spinal cord lesions in the form of single spinal multiple sclerosis (MS) plaque. All cases are considered as self control by measuring two controls above and below lesion.

Results: High statistically significant difference of fractional anisotropy (FA) between lesion and control with statistically significant difference of apparent diffusion coefficient (ADC) between lesion and control (Mann-Whitney Test p value < 0.05), resultant cut off value is 0.333 which gives higher specificity and sensitivity with efficacy 87.5%.

Conclusion: the resulted values of newly designed protocol give functional and numerical marker by which the diagnosis and prognosis will be more suitable.

Keywords: Spinal cord, DTI, FA and ADC.

INTRODUCTION:

Myelopathy describes any neurologic deficit related to the spinal cord which usually occurs due to compression of the spinal cord by osteophyte or extruded disc material in the cervical and dorsal spine. Other common sources of myelopathy are cord compression due to extra-dural mass caused by carcinoma metastasis to bone and trauma. Many primary neoplastic tumors, infectious, inflammatory, neurodegenerative, vascular, nutritional, and idiopathic disorders result in myelopathy[1].

Magnetic resonance imaging (MRI) is currently by far the most important imaging modality of the central nervous system (CNS). It provides excellent anatomical information about the spinal cord macrostructure[2,3].

The magnetic resonance (MR) shows the mass effect on the spinal cord which may be associated with abnormal signal intensity.
on T2-weighted imaging sequence yet it is still limited in predicting symptom severity as patients may have a varying tolerance of spinal cord compression. The T2W changes are often a late finding and may predict worse outcome despite decompression[4,5].

The diffusion tensor imaging (DTI) is an advanced non-invasive technique of magnetic resonance (MR) which enables visualization of the white matter tracts and assessment of their integrity not only through qualitative way but also in quantitative way by utilizing the diffusion of water molecules to act as a probe for assessing tissue microstructure[6,7].

The diffusion tensor imaging (DTI) results are quantified by two primary parameters: the apparent diffusion coefficient (ADC) value which refers to the overall diffusivity of the tissue irrespective of directional dependence, and the fractional anisotropy (FA) value which reflects the directional dependence of the diffusion process and is expressed as a relative number ranging from 0 to 1 that increases in relation to the anisotropic diffusion within the tissue being evaluated [8].

In the spinal cord compression the diffusion tensor imaging (DTI) and tractography patterns shows the intact versus disrupted fiber bundles and although it is not associated with the severity of symptoms[9,10].

Exclusion criteria any patients with contra-indication for MRI, e.g. an implanted magnetized device, pacemaker and claustrophobia, Patients with cervical or dorsal vertebral bodies fixation by screws.

- **MR diffusion tensor imaging technique**

Images were obtained using closed 1.5 Tesla MR System Acheiva Philips Magnet and phased array coil. Patient was in supine position with the head first. Different MRI sequences were obtained included sagittal T1 (TR 800 ms, TE 7.8), sagittal T2 (TR 2680, TE 100), axial FEE (TR 500, TE 9) and axial DTI (TR 7100, TE 70). Sagittal STIR sequence (TR 3500, TE 80) was done in patients with MS. Post processing acquisition of the resulted DTI imaging using Philips software for tractography (Philips extended MR workspace), by drawing similar region area of interest (ROI) size at area of lesion, areas above and below (control 1 and 2 respectively).

**RESULTS:**

The study included 16 patients, 8 patients with MS, 6 patients with disc lesions and 2 patients with bone metastasis.

The results between all lesions and control 1 showed highly significant FA value with mean of (0.35 ± 0.131 SD), (Mann-Whitney test p = 0.001), and significant ADC value with mean of (1.061 ± 0.454 SD) (Mann-Whitney test p = 0.031), while the results between all lesions and control 2 showed highly significant FA value with mean of (0.35 ± 0.131 SD) (Mann-Whitney test p = 0.002), and significant ADC value with mean of (1.061 ± 0.454 SD) (Mann-Whitney test p = 0.02).

The results also included FA cut off value of 0.333 between all lesions and control (1+2) groups with sensitivity 62.5%, specificity 100,-ve predictive value 84.2%,+ve predictive value 100% and accuracy 87.5 %. Cut off value of ADC was
The Role Of Diffusion Tensor Imaging (DTI) In Spinal Cord Pathology

1.36 which had sensitivity 75%, specificity 87.5%, -ve predictive value 87.5%, +ve predictive value 75% and accuracy 83.3%.

The results between MS plaques lesions and control 1 showed significant FA value with mean of (0.292 ± 0.087 SD) (Mann-Whitney test p = 0.029), and non significant ADC value with mean of (1.79 ± 0.53 SD) (Mann-Whitney test p = 0.218), while the results between MS plaques lesions and control 2 showed significant FA value with mean of (0.292 ± 0.087 SD) (Mann-Whitney test p = 0.011), non-significant ADC value with mean of (1.79 ± 0.53 SD) (Mann-Whitney test p = 0.119).

The results also included cut off value of FA =0.333 between MS lesions and control (1+2) groups which had sensitivity 75%, specificity 100%, -ve predictive value 88.9%, +ve predictive value 100% and accuracy 91.7% and cut off value of ADC =2.145 which had sensitivity 50%, specificity 100% -ve predictive value 80%, +ve predictive value 100% and accuracy 83.3%.

Fig. (1): ROC curve analysis showing the diagnostic performance of FA and ADC for discriminating patients with lesions (internal and compressive) from control (1+2)
The results between compressive (disc and metastatic) lesions and control 1 showed significant FA value with mean of (0.42 ± 0.147 SD) (Mann-Whitney test p = 0.048), and significant ADC value with mean of (1.44 ± 0.34 SD) (Mann-Whitney test p = 0.045), while the results between disc lesions and control 2 showed non-significant FA value with mean of (0.421 ± 0.147 SD) (Mann-Whitney test p = 0.08), and non-significant ADC value with mean of (144 ± 0.34 SD) (Mann-Whitney test p = 0.099).

The results also included cut off value of FA = 0.316 between compressive lesions and control (1+2) groups which had sensitivity 50%, specificity 100%, -ve predictive value 80%, +ve predictive value 100% and accuracy 83.3%. Cut off value of ADC = 1.36 which had sensitivity 75%, specificity 100%, -ve predictive value 88.9%, +ve predictive value 100% and accuracy 91%.

**DISCUSSION:**

MS is an acquired chronic immune-mediated inflammatory condition of the central nervous system, affecting both the brain and spinal cord. Cervical cord involvement is most frequent clinical site of involvement in
spinal MS, our study showed FA value is affecting even with subtle change in T2 signal of the spinal cord which agree with studies showed decreasing degree of FA values in early-stage lesions is parallel to the clinical prognosis with lesser change being correlated with better prognosis\(^{[12,13]}\).

Our study resulted the more the decreased the FA value, the more neurological symptoms patients had, this is in agree with study reporting decrease in FA value reflects axonal injury, correlation with clinical recovery has been seen; the lower the FA values, the more severe is the injury (figure 2,3), with the more serious neurological dysfunction and the worse outcome\(^{[14]}\).

On the other hand, early remyelination could result in the reconstruction of fasciculus anisotropy, leading to an increase in FA values which implies a better prognosis\(^{[15]}\). Furthermore, the decreasing of ADC values in acute lesions might be related to the proliferation of astrocytes and oligodendrocytes, which can represent remyelination and clinical recovery, also suggesting a more favorable outcome\(^{[16]}\), that represented in our study by increased FA and decreased ADC values in patient’s have multiple plaques.

MRI is the modality of choice for assessing cervical spondylosis\(^{[17]}\); our study showed decrease FA and increase ADC in mild disc lesion with no significant spinal cord changes in conventional MRI ,more decrease in FA, the more cord affection by disc lesion. This is agreed with paper showed MRI has limited role in the evaluation of spinal cord involvement. In chronic degenerative myelopathy caused by disk herniation or degenerative spinal canal stenosis, significant decrease of FA and increase of ADC has been found, including cases with no visible changes in the spinal cord on plain MRI (figure 4,5)\(^{[10,18]}\).

In recently published reports concerning contribution of DTI in cervical myelopathy, the authors have claimed that DTI proved to be more sensitive than conventional T2-weighted images in assessment of cervical degenerative myelopathy\(^{[10,19,20]}\). The decrease in the FA values may reflect the degree of microstructural disorganization of the spinal cord, suggesting either local extracellular edema or a smaller number of fibers matching a larger extracellular space, or both. On the other hand, minor lesions and edema with roughly preserved fibrillary microstructure of the spinal cord are not associated with major FA changes, as opposed to demyelination, cavitations and necrotic changes. Thus, the high FA values suggest that the microstructure of the spinal cord is preserved, even in cases with increased signal intensity of the spinal cord on T2-weighted images\(^{[19]}\).

Our study showed decrease in FA value with variable ADC according to type of lesion, this is matching with study showed a significant decrease of FA and variable ADC values has been found in extra-medullary tumors compressing the spinal cord (fig. 6). FA measurements proved to have high sensitivity and specificity in the detection of spinal cord pathology in patients with extra-medullary spinal canal tumors\(^{[22]}\).
Fig. 2 Case 1: 35 year old female patient known case of MS complaining of recent neurological symptoms of both upper limb.

Sagittal T2 with demyelinating plaque opposite C6/7 presented with bright T2 signal and DTI tables ROI reading shows low FA and high ADC value at C6/7 level.

Fig. 3 Case 2: 32 year old female patient presented with rapidly progressing numbness in both arm associated with unilateral loss of vision, recently clinically proved to be MS.

Sagittal STIR with demyelinating plaque opposite C5 and bright T2 signal, DTI tables ROI reading shows low FA and high ADC value at C5 level.

Fig. 4 case 3:55 year old female patient with cervical disc lesions mainly at (A) sagittal T2 with FA and ADC ROI readings. C6/7 level showed low FA value and high ADC value. (B) post processing tractography shows intact spinal cord fiber integrity.
Fig. 5 case 4: 46 year old male patient with cervical disc lesions.

(A) sagittal T2WI with FA and ADC ROI readings shows C3/4 low FA value and high ADC value (B) axial T2WI at the level of C3-C4 central disc bulge with effacing anterior CSF space and abutting cervical spinal cord.

Fig. 6 Case 5: 61 year old male patient known case of cancer colon complaining of recent neurological symptoms of both lower limbs and back pain.

Sagittal T2 with reduced height of D10 with rounded posterior margin indenting the spinal cord and DTI tables ROI reading shows low FA and high ADC value at D10 level.
Conclusion:

The study showed that the value of the newly additional sequence (DTI, DTT) with its dual measurable values ADC, FA helps in confirming early functional early affection of the spinal cord even before apparent change of cord signal, which has great impact of early diagnosis and prognosis.

List of abbreviations:

ADC: apparent diffusion coefficient.
DTI: diffusion tensor imaging
FA: fractional anisotropy.
MRI: Magnetic resonance imaging.
MS: multiple sclerosis.
DTT: diffusion tensor tractography.
ROI: region area of interest.
